

What is the main energy storage system?

The main energy storage system is the high-grade thermal energy storage. The rest of the air is kept in the low-grade thermal energy storage, which is between points 8 and 9. This stage is carried out to produce pressurized air at ambient temperature captured at point 9. The air is then stored in high-pressure storage (HPS).

Where can compressed air energy be stored?

The number of sites available for compressed air energy storage is higher compared to those of pumped hydro [1]. Porous rocks and cavern reservoirs are also ideal storage sites for CAES. Gas storage locations are capable of being used as sites for storage of compressed air.

What is compressed air energy storage (CAES)?

Compressed air energy storage (CAES) is an effective solution for balancing this mismatch and therefore is suitable for use in future electrical systems to achieve a high penetration of renewable energy generation.

Can gas storage locations be used for compressed air storage?

Gas storage locations are capable of being used as sites for storage of compressed air. Today, several research activities are being carried out to explore the application of CAES on small scale projects, following their successful integration on large scale renewable energy systems [2].

Can adiabatic compressed air energy storage be combined with a gas turbine?

Combining an adiabatic compressed air energy storage (A-CAES) with a gas turbine (GT) can address any sudden changes in demand, but a comprehensive analysis of the integration effects between A-CAES and GT is needed. This study introduced a regenerative A-CAES-GT hybrid system with two thermal integrations: preheating and regeneration.

How to analyze compressed air energy storage systems?

Analysis of compressed air energy storage systems is usually conducted by taking both compression and expansion stages into consideration using ideal gas laws. Expanders' mechanical work is first transformed.
