

Generator cooling and air guiding

What are the different types of generator cooling systems?

Each generator set manufacturer offers different options for design of the cooling system. The two most common styles of cooling systems are closed loop and open loop systems. Closed loop systems incorporate cooling pump (s), cooling fan and radiator (s) located on a skid as an all in one unit.

How does a generator cooling system work?

An ethylene glycol based coolant is circulated through the cooling system components. Three common cooling system configurations are: Single Pump Single Loop (SPSL) - SPSL systems are common in smaller to mid-size generator applications. Operation for this system as follows: o Engine starts, direct drive pump is driven and fan clutch is rotating.

What are the components of a generator cooling system?

Coolant System - Each generator application can have a different cooling system configuration. Below is a general list of components: o Coolant pump- Depending on engine size, belt or gear driven. Circulates coolant throughout cooling system. o Radiator - Can be single or twin radiator design.

What is an air cooled generator?

As it does, the air is cooled which, in turn, keeps the generator cool. Air cooled systems have some limits including the risk of overheating. However, air cooled systems are mostly restricted to small standby and portable generators that produce up to 22 kilowatts of power per unit.

Why do generators need to be cooled?

By consistently cooling the generator, it is possible to minimize the risk of any damage to the generator itself. Ultimately, this reduces frustration and prevents the need for repairs. Knowing the value of cooling generators, it is then important to understand how the best air-cooled systems work.

How does a liquid cooled generator work?

There are numerous types of liquid-cooled systems. Some operate using oil while others use coolants. Hydrogen is another cooling element. A liquid-cooled system features a water pump that moves the coolant around the engine using a number of hoses. The heat from the generator transfers naturally to the coolant, cooling the unit.
