What is a wind turbine blade design?

The fundamental goal of blade design is to extract as much kinetic energy from the wind as possible while minimizing losses due to friction and turbulence. To achieve this, engineers focus on various aspects of blade design. One of the most obvious factors affecting a wind turbine's efficiency is the length of its blades.

What are the aerodynamic design principles for a wind turbine blade?

The aerodynamic design principles for a modern wind turbine blade are detailed, including blade plan shape/quantity, aerofoil selection and optimal attack angles. A detailed review of design loads on wind turbine blades is offered, describing aerodynamic, gravitational, centrifugal, gyroscopic and operational conditions.

Do wind turbines use horizontal axis rotors?

The review provides a complete picture of wind turbine blade design and shows the dominance of modern turbines almost exclusive use of horizontal axis rotors. The aerodynamic design principles for a modern wind turbine blade are detailed, including blade plan shape/quantity, aerofoil selection and optimal attack angles.

How much power does a wind turbine blade produce?

The baseline (Bak et al., 2013) wind turbine blade has been upscaled to achieve 20 MW power using the above-described methodologies. Wind turbine blades with a larger span will produce more energy. Large blades provide a wide area for the airflow to pass across, resulting in higher rotational power and force (Hau, 1981).

How does a wind turbine blade design affect efficiency?

To achieve this, engineers focus on various aspects of blade design. One of the most obvious factors affecting a wind turbine's efficiency is the length of its blades. Longer blades have a larger surface area and can capture more wind energy. However, longer blades also come with challenges, such as increased weight and higher manufacturing costs.

What if a turbine blade has no pitch?

Were the blade to have no pitch (0 degrees), the moment in extreme winds would be 7386 kN-m. So long as we are able to pitch our blade, however, it is possible to keep even extreme winds from damaging the turbine blade.
